#### **NAME**

getgroups, setgroups – get/set list of supplementary group IDs

## **SYNOPSIS**

```
#include <sys/types.h>
#include <unistd.h>
int getgroups(int size, gid_t list[]);
#include <grp.h>
int setgroups(size_t size, const gid_t *list);
```

Feature Test Macro Requirements for glibc (see **feature\_test\_macros**(7)):

setgroups(): \_BSD\_SOURCE

## **DESCRIPTION**

**getgroups**() returns the supplementary group IDs of the calling process in *list*. The argument *size* should be set to the maximum number of items that can be stored in the buffer pointed to by *list*. If the calling process is a member of more than *size* supplementary groups, then an error results. It is unspecified whether the effective group ID of the calling process is included in the returned list. (Thus, an application should also call **getegid**(2) and add or remove the resulting value.)

If *size* is zero, *list* is not modified, but the total number of supplementary group IDs for the process is returned. This allows the caller to determine the size of a dynamically allocated *list* to be used in a further call to **getgroups**().

**setgroups**() sets the supplementary group IDs for the calling process. Appropriate privileges (Linux: the **CAP\_SETGID** capability) are required. The *size* argument specifies the number of supplementary group IDs in the buffer pointed to by *list*.

## **RETURN VALUE**

On success, **getgroups**() returns the number of supplementary group IDs. On error, -1 is returned, and *errno* is set appropriately.

On success, **setgroups**() returns 0. On error, -1 is returned, and *errno* is set appropriately.

## **ERRORS**

## **EFAULT**

list has an invalid address.

getgroups() can additionally fail with the following error:

#### EINVAL

size is less than the number of supplementary group IDs, but is not zero.

setgroups() can additionally fail with the following errors:

#### **EINVAL**

size is greater than NGROUPS\_MAX (32 before Linux 2.6.4; 65536 since Linux 2.6.4).

## **ENOMEM**

Out of memory.

# **EPERM**

The calling process has insufficient privilege.

### **CONFORMING TO**

SVr4, 4.3BSD. The **getgroups**() function is in POSIX.1-2001. Since **setgroups**() requires privilege, it is not covered by POSIX.1-2001.

# **NOTES**

A process can have up to **NGROUPS\_MAX** supplementary group IDs in addition to the effective group ID. The set of supplementary group IDs is inherited from the parent process, and preserved across an **execve**(2).

The maximum number of supplementary group IDs can be found using **sysconf**(3):

```
long ngroups_max;
ngroups_max = sysconf(_SC_NGROUPS_MAX);
```

The maximum return value of **getgroups**() cannot be larger than one more than this value.
