#### **NAME**

posix\_fadvise - predeclare an access pattern for file data

## **SYNOPSIS**

## #define \_XOPEN\_SOURCE 600

#include <fcntl.h>

int posix\_fadvise(int fd, off\_t offset, off\_t len, int advice);

#### DESCRIPTION

Programs can use **posix\_fadvise**() to announce an intention to access file data in a specific pattern in the future, thus allowing the kernel to perform appropriate optimizations.

The *advice* applies to a (not necessarily existent) region starting at *offset* and extending for *len* bytes (or until the end of the file if *len* is 0) within the file referred to by *fd*. The advice is not binding; it merely constitutes an expectation on behalf of the application.

Permissible values for advice include:

## POSIX FADV NORMAL

Indicates that the application has no advice to give about its access pattern for the specified data. If no advice is given for an open file, this is the default assumption.

## POSIX FADV SEQUENTIAL

The application expects to access the specified data sequentially (with lower offsets read before higher ones).

# POSIX\_FADV\_RANDOM

The specified data will be accessed in random order.

### POSIX FADV NOREUSE

The specified data will be accessed only once.

# POSIX FADV WILLNEED

The specified data will be accessed in the near future.

#### POSIX FADV DONTNEED

The specified data will not be accessed in the near future.

#### **RETURN VALUE**

On success, zero is returned. On error, an error number is returned.

## **ERRORS**

#### **EBADF**

The fd argument was not a valid file descriptor.

#### **EINVAL**

An invalid value was specified for advice.

#### **ESPIPE**

The specified file descriptor refers to a pipe or FIFO. (Linux actually returns EINVAL in this case.)

## **VERSIONS**

**posix\_fadvise()** appeared in kernel 2.5.60. Glibc support has been provided since version 2.2.

# **CONFORMING TO**

POSIX.1-2001. Note that the type of the *len* argument was changed from *size\_t* to *off\_t* in POSIX.1-2003 TC1.

### NOTES

Under Linux, POSIX\_FADV\_NORMAL sets the readahead window to the default size for the backing device; POSIX FADV SEQUENTIAL doubles this size, and POSIX FADV RANDOM disables file

readahead entirely. These changes affect the entire file, not just the specified region (but other open file handles to the same file are unaffected).

**POSIX\_FADV\_WILLNEED** initiates a non-blocking read of the specified region into the page cache. The amount of data read may be decreased by the kernel depending on virtual memory load. (A few megabytes will usually be fully satisfied, and more is rarely useful.)

In kernels before 2.6.18, **POSIX\_FADV\_NOREUSE** had the same semantics as **POSIX\_FADV\_WILL-NEED**. This was probably a bug; since kernel 2.6.18, this flag is a no-op.

**POSIX\_FADV\_DONTNEED** attempts to free cached pages associated with the specified region. This is useful, for example, while streaming large files. A program may periodically request the kernel to free cached data that has already been used, so that more useful cached pages are not discarded instead.

Pages that have not yet been written out will be unaffected, so if the application wishes to guarantee that pages will be released, it should call **fsync**(2) or **fdatasync**(2) first.

#### **BUGS**

In kernels before 2.6.6, if *len* was specified as 0, then this was interpreted literally as "zero bytes", rather than as meaning "all bytes through to the end of the file".
